Environment America Research & Policy Center is a 501(c)(3) organization. We are dedicated to protecting America's air, water and open spaces. We investigate problems, craft solutions, educate the public and decision makers, and help Americans make their voices heard in local, state and national debates over the quality of our environment and our lives. For more information about Environment America Research & Policy Center or for additional copies of this report, please visit www.environmentamerica.org/center.

Frontier Group conducts independent research and policy analysis to support a cleaner, healthier and more democratic society. Our mission is to inject accurate information and compelling ideas into public policy debates at the local, state and federal levels. For more information about Frontier Group, please visit www.frontiergroup.org.

Executive Summary

Power plants continue to release large amounts of toxic pollutants, including mercury, into our air. In 2010, two-thirds of all airborne mercury pollution in the United States came from the smokestacks of coal-fired power plants. In other words, power plants generate more airborne mercury pollution than all other industrial sources combined.*

Mercury is a potent neurotoxicant. Mercury exposure during critical periods of brain development can contribute to irreversible deficits in verbal skills, damage to attention and motor control, and reduced IQ.

In 2011, the U.S. Environmental Protection Agency (EPA) developed the first national standards limiting mercury and other toxic air pollution from existing coal- and oil-fired power plants. Implementing these standards will protect public health.

Coal-fired power plants are a major source of airborne mercury pollution.

- The Big Brown Steam Electric Station and Lignite Coal Mine in Fairfield, Texas, emitted 1,610 pounds of mercury pollution into our air in 2010, the most of any industrial facility in the nation.
- This amount is significant because mercury is so potent. Distributed over a wide area, just fractions of an ounce of mercury can contaminate local and regional water bodies, making resident fish unsafe to eat. All 50 states currently have advisories warning women and children not to eat local fish due to mercury contamination.
- Of the top 10 biggest mercury-polluting power plants in the country, six are located in Texas, with one each in Alabama, Louisiana, Missouri and Ohio. Table ES-1 lists these top 10 biggest mercury polluters.
- Among all states nationwide, Texas ranked first in terms of overall airborne mercury pollution produced by power plants in 2010. Ohio ranked second, followed by Pennsylvania in third. (See Table ES-2.)
- Just five companies were responsible for more than one-third of all power plant mercury emissions in 2010, led by American Electric Power with 6,200 pounds. (See Table ES-3.)

* The data presented in this report focus on power plant emissions data reported to the U.S. Environmental Protection Agency's *Toxics Release Inventory* (TRI). Industries that are not required to report to TRI, or facilities with emissions below the reporting threshold, will not be represented in the data. For more detail, see the Methodology section on page 18.

Mercury pollution threatens public health.

- Largely due to emissions from coal-fired power plants, mercury contamination in our environment is widespread. After leaving the smokestack, mercury falls to the ground in rain or snow, contaminates waterways, and accumulates in fish. Eating contaminated fish is the main source of human exposure to mercury.
- Mercury is a potent neurotoxicant. During critical windows of brain development that occur *in utero* and in the first year or two of a child's life, mercury exposure can lead to irreversible deficits in attention and motor control, damage to verbal skills, and reduced IQ.
- One in 10 women of childbearing age in the United States has enough mercury in her blood to put her child at risk of developmental damage should she become pregnant.

Figure ES-1: Power Plant Sources of Airborne Mercury Pollution, 2010

Each circle in this map represents a power plant that reported mercury pollution in 2010. The area of the circle is directly proportional to the amount of mercury the plant emitted.

New EPA standards will limit mercury pollution from power plants and protect public health.

- Under the authority of the Clean Air Act, EPA has developed the first national standard limiting releases of mercury and other toxic air pollutants from existing coal- and oil-fired power plants. As proposed in March 2011, this standard will require power plant owners to cut overall emissions of mercury by more than 90 percent using widely available, proven pollution control technologies.
- Similar standards affecting other industries have successfully reduced mercury contamination of fish in local waterways.
- As proposed, the new emissions standard will improve public health. EPA estimates that for every dollar spent to reduce pollution from power plants, the American public and American businesses will see up to \$13 in health and economic benefits. In total, the rules could provide as much as \$140 billion worth of benefits annually.
- EPA should finalize the rules as proposed. Congress should support this common-sense action.

Introduction

In 1970, President Nixon sat down in the Roosevelt Room of the White House to sign the Clean Air Act into law. He said, “I think that the year of 1970 will be known as the year of the beginning, in which we really began to move on the problems of clean air and clean water and open spaces for the future generations of America.”¹

How right he was. 1970 was a landmark year for action to protect our health, our air and our water. It was also the beginning of a long road – and we still have not yet reached our destination.

Although America has made great strides in cleaning up sources of air pollution from automobiles to factories over the last four decades, air pollution remains a serious and persistent problem. Moreover, our increasing understanding of the dangers posed by toxic pollutants only brings the terrible toll that air pollution causes into greater focus. Every year, air pollution kills tens of thousands of Americans, triggers millions of asthma attacks, and causes millions of missed work and school days due to pollution-related illness.² Air pollution costs us hundreds of billions of dollars a year in sickness and lost productivity.³

Industry resistance to common-sense measures that would reduce pollution and protect the health of American families has unnecessarily dragged out the process of cleaning the air. Owners of coal-fired power plants, in particular, have been granted ample time to clean up over the years. Grandfathered under provisions of the Clean Air Act that were intended to require power plants to install better

Photo: Claudia Meyer

pollution controls at the time of any major modifications, many coal-fired power plants have avoided installing effective emissions controls for decades.

Coal-fired power plants are a particularly large source of mercury pollution – a scourge that affects hundreds of thousands of children across the country. By 1990, when Congress rewrote the Clean Air Act to demand faster cleanup of toxic air pollution, coal-fired power

plants produced about as much airborne mercury pollution as municipal waste incinerators and medical waste incinerators.⁴ However, in response to the 1990 Clean Air Act Amendments, mercury emissions from incinerators are down by well over 95 percent.⁵ In contrast, almost half of the nation's fleet of coal-fired power plants still lacks modern emissions control technology.⁶

This year, EPA has proposed to finally require all existing coal- and oil-fired power plants to reduce toxic pollution and safeguard our health. It is long past time for these plants to clean up and to compete on an equal playing field with other power generating facilities under a national emissions standard. Once the new standard becomes final, perhaps 2011, too, can be known as the year in which we “really began to move on the problems of clean air and clean water and open spaces for the future generations of America.”

Mercury Pollution Threatens Public Health

Mercury is a potent neurotoxicant.⁷ Children are particularly vulnerable to the harmful impacts of mercury during critical windows of development that occur before birth and through the first few years of life.⁸ Mercury exposure can lead to irreversible deficits in verbal skills, damage to attention and motor control, and reduced IQ.

Largely due to emissions from coal-fired power plants, mercury contaminates waterways across the United States, from coastal bays to the Great Lakes. Mercury does not decompose in the environment. Rather, it can accumulate in fish and throughout the food chain, all the way to humans. People are primarily exposed to mercury through eating contaminated fish. Every state in the country has issued some form of advisory warning about the consumption of mercury-contaminated fish from local waters.

Scientists at the U.S. Environmental Protection Agency have estimated that one in 10 women of childbearing age in the United States has enough mercury in her bloodstream to risk damage to her child's brain development should she become pregnant.⁹ In other words, between 320,000 and 640,000 children born every year are exposed to mercury at levels associated with measurable developmental damage.¹⁰

Mercury Is Toxic to Human Development

As documented by the U.S. National Academy of Sciences, children exposed to low-dosage levels of mercury while in the womb can develop brain damage, leading to delayed language development, deficits in verbal skills, damage to attention and motor control, and reduced IQ.¹¹ The effects appear irreversible. Scientists have found that deficits due to *in utero* exposure still persist at age 14.¹²

Even adults are vulnerable to mercury pollution. Eating contaminated fish at any age can cause deficits in brain function, as well as fertility and cardiovascular problems.¹³

Researchers at Mt. Sinai School of Medicine, Harvard Medical School, Boston Children's Hospital and the Albert Einstein College of Medicine estimate that mercury pollution costs the nation \$8.7 billion annually in diminished intelligence of the population and resulting lost productivity.¹⁴

Mercury Contamination Is Widespread

Elemental mercury occurs naturally in our environment and can be found in coal and other underground rock deposits. When power plants burn coal, they emit mercury and other toxic pollutants into the air. After leaving the power plant smokestack, mercury pollution falls to the ground in rain or snow and then washes into lakes, streams and the ocean.

Mercury does not readily decompose in the environment. Instead, small organisms can transform it into mercury compounds that do not readily leave the body. These compounds build up in aquatic organisms and tend to increase in concentration in species at the top of the food chain. Species that tend to have high levels of mercury include larger freshwater fish and saltwater species such as tuna, swordfish and shark. People who eat contaminated fish end up with mercury that builds up in their bodies.¹⁵

According to the United States Environmental Protection Agency, mercury pollution impairs nearly 5,000 bodies of water across the country.¹⁶ Mercury contamination affects:¹⁷

- More than 14 million acres of bays, estuaries, lakes, reservoirs and ponds;
- More than 60,000 miles of rivers and streams; and
- More than 6,600 miles of coastal shoreline.

Every state in the United States has issued an advisory warning against the consumption of species of fish that tend to have dangerous levels of mercury.¹⁸ Every square inch of the Great Lakes is under a mercury advisory, along with thousands of smaller water bodies across the country.¹⁹

Scientists at the U.S. Environmental Protection Agency have estimated that one in 10 women of childbearing age in the United States has enough mercury in her bloodstream to risk damage to her child's brain development should she become pregnant.

Power Plants Continue to Emit Large Amounts of Mercury Pollution

Coal-fired power plants are the largest source of airborne mercury emissions in America. In 2010, two-thirds of all airborne mercury pollution came from the smokestacks of these power plants.²⁰ In other words, coal-fired power plants together generate more airborne mercury pollution than all other sources – including incinerators, steel mills and cement manufacturing plants – combined.

In total, power plants emitted 66,050 pounds of mercury pollution into the air in 2010. This amount is significant. Very small amounts of mercury can contaminate local and regional water bodies, making resident fish unsafe to eat.²¹

The most polluting industrial facility in the nation – the Big Brown Steam Electric Station and Lignite Coal Mine in Fairfield, Texas – emitted 1,610 pounds of mercury pollution in 2010. Of the top 10 biggest mercury-polluting power plants in the country, six are located in Texas, with one each in Alabama, Louisiana, Missouri and Ohio. Table 1 lists the top 25 biggest mercury polluters out of the 457 power facilities that reported mercury emissions to the EPA’s Toxics Release Inventory in 2010.

New Pollution Standards Are Needed to Clean Up Power Plants

In December 2011, the U.S. Environmental Protection Agency (EPA) will finalize new standards – officially known as Mercury and Air Toxics Standards for Power Plants – requiring existing coal- and oil-fired power plants to clean up their emissions of mercury and other toxic air pollution.²³

This safeguard has been in development for more than 20 years. In 1990, Congress revised the landmark Clean Air Act, requiring EPA to take greater action to reduce toxic air pollution, including emissions of mercury, to protect America’s children and overall public health. The law gave EPA the tools to require regulated industries to install the best emissions control technology available. In 2000, after many years of study, EPA determined that toxic pollution from coal- and oil-fired power plants should be regulated. New rules were to be finalized by 2002.

In January 2004, EPA drafted a broad emission standard based on the best available toxic pollution control technology, and also a much weaker alternative cap-and-trade system focused on mercury pollution. The power plant industry vigorously opposed the technology-based standards. In response to this pressure, in 2005 EPA asserted that pollution from coal- and oil-fired power plants did not need strict regulation, and instead finalized the weaker cap-and-trade program, called the Clean Air Mercury Rule.

Fourteen states and dozens of public health and environmental organizations – including Environment

Photo: Keith Syvinski

America – filed suit against this decision.²⁴ In 2008, a federal Circuit Court agreed with public health and environmental advocates, ruling that EPA could not, as it had, exempt the utility industry from regulation of toxic air pollution and that EPA must therefore withdraw the Clean Air Mercury Rule.²⁵ Late in 2008, the coalition of public health and environmental groups sued the agency, seeking a new enforceable deadline for EPA to issue technology-based standards for toxic air pollution from power plants.²⁶

In 2010, advocates and EPA agreed that EPA would propose new standards in March 2011 and finalize them in November 2011, despite resistance from the utility industry.²⁷ Later, advocates and EPA agreed that the final standard would be issued in December 2011 to allow EPA time to fully consider the public comments it had received.²⁸

If finalized as proposed, the new standard will require many power plants to install widely available, proven pollution control technologies, such as activated carbon injection.²⁹ Slightly more than half of all coal-fired power plants already deploy some of the pollution control equipment capable of delivering the performance necessary to meet the new standard.³⁰ The remaining coal-fired power plants – the top polluters identified in this report – will have to clean up. For the first time, all power plants will have to operate on a level playing field across the country.

If finalized as proposed and implemented as required by the Clean Air Act, the rules will reduce overall power plant emissions of mercury by more than 90 percent by mid-2015.³¹ Similar standards affecting incinerators, power plants and other industries have been implemented in some states. These actions have successfully reduced mercury emissions – resulting in significant declines in mercury contamination of fish in local waterways.³² A national standard will reduce mercury pollution and fish contamination nationwide, benefiting everyone.

EPA action will reduce public exposure to mercury and other toxic air pollutants, protecting the health of every American – especially children. In addition to reducing the insidious damage to brain development caused by mercury, the new standard will have broad health benefits by reducing emissions of other toxic metals as well as small particulates and sulfur dioxide. EPA estimates that when the standard is fully implemented – which could be up to four years after it goes into effect – reduced emissions will annually prevent:³³

- 17,000 premature deaths,
- 11,000 heart attacks,
- 12,000 emergency room visits and hospital admissions,
- 120,000 cases of childhood asthma symptoms, and
- 850,000 fewer days of work missed due to illness.

According to EPA, every dollar spent to reduce pollution from power plants will deliver up to \$13 in health and economic benefits for the American public and American businesses.³⁴ In total, the new safeguard could provide as much as \$140 billion worth of benefits annually.³⁵ These figures do not count additional health benefits that will accrue from reduced levels of certain toxic organic air pollutants or the environmental benefits of the rule for ecosystems and wildlife.

The proposed Mercury and Air Toxics Standards represent a clear, common-sense step that will significantly improve public health. EPA should finalize the standards as proposed. Additionally, Congress should support this action on behalf of all American citizens.

Methodology

The emissions data presented in this report are derived from the U.S. Environmental Protection Agency (EPA), *Toxics Release Inventory, 2010 TRI Dataset*, 27 October 2011, available at www.epa.gov/tri/tridata/preliminarydataset/index.html. Toxics Release Inventory emissions data are self-reported by regulated facilities. The dataset we used was the first iteration of the 2010 inventory. EPA may update this information over time to capture late reporting and revisions.

We first selected any emitter listed in the database involved in electricity generation by choosing facilities with a primary or secondary industry classification code (or NAICS code) beginning with 22111. We then examined emissions of mercury and mercury compounds to the air, including both fugitive emissions and emissions through power plant smokestacks. The analysis does not count any mercury emissions reported to TRI that do not involve atmospheric release.

The data represent only industries that are required to submit data to EPA under the Toxics Release Inventory program, and facilities with emissions exceeding the reporting threshold of 10 pounds per year, and is not necessarily a comprehensive listing of all power plants or mercury emitters in each state.³⁶

²⁰ The data presented in this section focuses on power plant emissions data reported to the the U.S. Environmental Protection Agency's Toxics Release Inventory (TRI). Industries not required to report to TRI, or facilities with emissions below the reporting threshold, will not be represented in the data. For more detail, see the Methodology section.
